8.23 TALBOT COUNTY

This chapter presents information about stream conditions of potential management interest in Talbot County based on the 2000-2004 Maryland Biological Stream Survey (MBSS) results. Information from MBSS data collected between 1994 and 1997 can be found in MDNR 2001u.

8.23.1 Ecological Health

Based on the three ecological health indicators used by the MBSS, the overall condition of Talbot County streams during 2000-2004 was Fair (Figure 8-186). The FIBI results indicate that 23% of the streams in the county were in Good condition, and 66% rated Good using the BIBI. In contrast, 23% of the streams in the county scored as Very Poor using the CBI, while about 28% scored as Good and 50% scored as Fair.

Sites with high IBI scores were generally found in the eastern portion of the county. In contrast, sites in the general vicinity of the Route 50 corridor consistently rated as Very Poor. The highest rated stream in Talbot County using the Combined Biotic Index (CBI) was an unnamed tributary to Tuckahoe Creek, while the lowest rated streams included Tanyard Branch, an unnamed tributary to Windmill Branch and Hunting Creek (Table 8-45). Based on Stream Waders data, sites rated as Poor or Very Poor for benthic macroinvertebrates in the county were outnumbered by sites rated Good or Fair by a factor of two (Table 8-46). Only a single Stream Waders site, in the Wye River watershed, received a rating of Good.

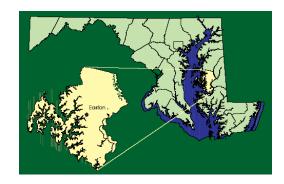

8.23.2 Physical Habitat

8.23.2.1 Overall Condition

Based on the Physical Habitat Index (PHI), only 5% of the streams in Talbot County had Minimally Degraded habitat, 65% had Partially Degraded habitat, and 23% had Degraded habitat (Figure 8-187). No streams in the county were rated as having Severely Degraded habitat. Sites rated as having Minimally Degraded physical habitat were located in the southernmost and westernmost sections of the county.

8.23.2.2 Trash

Over 73% of the stream miles in Talbot County were rated Optimal for trash (Figure 8-188). In contrast, 5% of streams were rated as Marginal and none were rated Poor for trash. No geographic trend was evident.

8.23.2.3 Channelization

About 34% of the stream miles in Talbot County were channelized (Table 8-4). The type of channelization found at MBSS sites was earthen ditches. The channelized sites occurred in the central portion of the county (Figure 8-189).

8.23.2.4 Inadequate Riparian Buffer

No stream miles in Talbot County were devoid of riparian buffers during the 2000-2004 MBSS (Table 8-3; Figure 8-190). In addition, no sites sampled had severe breaks in existing riparian buffers. Additional information about buffer breaks, analyzed by county, is provided in: 2000-2004 Maryland Biological Stream Survey Volume 10: Riparian Zone Conditions (http://www/dnr/ Maryland.gov/streams/pubs/ea05-7_riparian.pdf).

8.23.2.5 Eroded Banks/Bedload Movement

Nearly 44% of the stream miles in Talbot County were rated as Poor for bank erosion (Figure 8-191). An additional 22% of streams were rated as Marginal. The remaining 34% of stream miles in the county were rated as having minimal (Optimal) bank erosion problems. There were no apparent geographic trends in the distribution of erosion or bar formation problems in the county.

Nearly 84% of the stream miles in Talbot County were rated as having minor or moderate bar formation (Figure 8-191). An additional 16% had extensive bar formation, while no streams were devoid of bars.

8.23.3 Key Nutrients

8.23.3.1 Nitrate-Nitrogen

Nearly 77% of the stream miles in Talbot County had nitrate-nitrogen levels elevated over 1 mg/l (Figure 8-192). About 33% of all stream miles had levels over

5 mg/l, the threshold at which biological impacted have been documented. No geographic trends were evident, with the exception that the sites around Easton had low levels of nitrate-nitrogen.

8.23.3.2 Total Phosphorus

More than 88% of the stream miles in Talbot County had elevated levels of total phosphorus (Figure 8-193). Over 16% of stream miles had levels above the threshold at which biological impacts may occur. No geographic trends in total phosphorus levels were evident.

8.23.4 Stream and River Biodiversity

To provide a means to prioritize stream systems for biodiversity protection and restoration within each county and on a statewide basis, a tiered watershed and stream

reach prioritization method was developed. Special emphasis was placed on state-listed species, stronghold watersheds for state-listed species, and stream reaches with one or more state-listed aquatic fauna. Fauna considered included stream salamanders, freshwater fishes, and freshwater pollution-sensitive mussels. Rare, macroinvertebrates collected during the 1994-2004 MBSS were also used to identify the suite of watersheds necessary to conserve the full array of known stream and river biota in Maryland. A complete description of the biodiversity ranking process is found in: 2000-2004 Maryland Biological Stream Survey Volume 9: Stream and Riverine Biodiversity (http://www/dnr/Maryland. gov/streams/pubs/ea05-6_biodiv.pdf).

Of the four watersheds found in Talbot County, Tuckahoe Creek and Upper Choptank River were classified as Tier 1, meaning that these watersheds serve as strongholds for one or more state listed aquatic species (Figure 8-194). In contrast, the Honga River/Little Choptank River/Lower Choptank watershed was among the lower ranking for stream and river biodiversity in the state (61st of

84). Any reaches that had either state-listed or GCN species, or high intactness values were highlighted to facilitate additional emphasis in planning restoration and protection activities.

8.23.5 Stressors

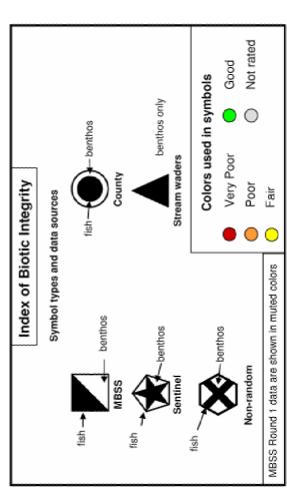

At 78% of stream miles, the most extensive stressor characterized by the MBSS in Talbot County during the 2000-2004 MBSS was non-native terrestrial plants in the riparian zone (Figure 8-5). Other stressors found were: streams with eroded banks (66% of stream miles); non-native aquatic fauna (present in 66% of stream miles); low dissolved oxygen (23% of stream miles); channelized streams (observed in 23% of stream miles); high nitrate-nitrogen (33%); and streams with > 5% urban land use upstream (16% of stream miles).

AN IMPORTANT NOTE ON BIODIVERSITY MANAGEMENT

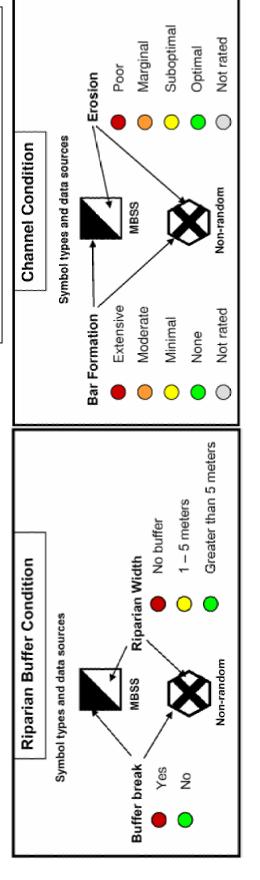

Perhaps the largest ongoing natural resources restoration and protection effort in Maryland is associated with the Chesapeake Bay. In most cases, freshwater biodiversity is not specifically considered during placement and prioritization of Bay restoration and protection projects. In this report and in the more detailed volume in the series on aquatic biodiversity, a system of biodiversity ranking is presented to provide counties and other stewards with a means to plan appropriate protection and restoration activities in locations where they would most benefit stream and river species. Given the historically low level of funding for biodiversity protection and restoration in Maryland and elsewhere, the potential benefit of incorporating freshwater biodiversity needs into other efforts is quite large.

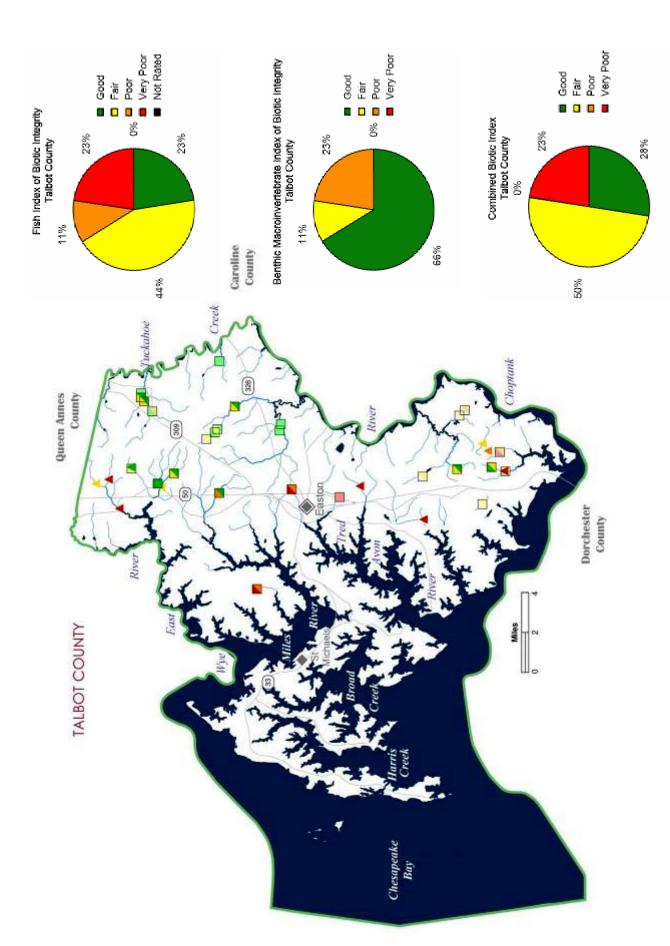

However, it is important to note that although freshwater taxa are the most imperiled group of organisms in Maryland, other groups and individual species not typically found in freshwater habitats are also at high risk and constitute high priority targets for conservation. In addition, freshwater taxa that prefer habitats such as small wetlands may not be well-characterized by the ranking system employed here. To conserve the full array of Maryland's flora and fauna, it is clearly necessary to use other, landscape-based tools and consider factors such as maintaining or reconnecting terrestrial travel corridors.

Key to MBSS 2000-2004 County Maps

had state-listed fish, aquatic herpetofauna, or freshwater Non-stronghold watershed with one or more state-listed Not of the above, but a biodiversity conservation waterthat must be conserved to keep all native fishes, aquatic sensitive benthic macroinvertebrates extant in Maryland. Stronghold watershed for one or more non-state listed GCN fish, aquatic herpetofauna, or freshwater mussels, no state-listed fish, aquatic herpetofauna, or freshwater shed. In other words, part of the network of watersheds Stronghold watershed for one or more non-state listed aquatic herpetofauna, or freshwater mussels, that also herpetofauna, freshwater mussels, and rare, pollution population) for one or more state-listed fish, aquatic species of greatest conservation need (GCN) fish, fish, aquatic herpetofauna, or freshwater mussels Stronghold watershed (most robust remaining herpetofauna, or freshwater mussels.
